Abstract (en)
[origin: WO9405391A1] A constructional toy component (13) which has on at least one edge (11), two portions (15, 16) each of which has associated therewith one of two complementary members (19, 18), the arrangement being such that when two similar edges are brought into abutment but in the opposite sense, the complementary members (19, 18) can interengage if one of the components is initially flexed to effectively vary the spacing between the complementary members thereon. In one form of the invention, the edges are formed of rod like members and thus the component is basically defined by a peripheral frame. After engagement is completed, and the flexure is released, there is effectively no deformation of either component, but the components are held together by the interrelationship of the complementary members.
