Abstract (en)

[origin: EP0615400A2] Gaseous alcohol and steam emanating from food being heated are detected by an alcohol sensor (11) and a steam sensor (12) respectively. A control circuit (16) obtains maximum values V_{Amax} and V_{Gmax} serving as reference values from detection voltages generated by the alcohol and steam sensors (11, 12). Change rates DELTA A (V_A/V_{Amax}) and DELTA G (V_G/V_{Gmax}) are obtained on the basis of detection voltages V_A and V_G detected a predetermined time (40 seconds, for example) after initiation of the heating and a ratio r of the change rates is obtained from the expression, $r=(1-\text{DELTA A})/(1-\text{DELTA G})$. The control circuit (16) compares a value of the ratio r with a threshold set for each kind of food to discriminate the kind of the food, thereby setting a subsequent heating time to execute the heating. Since the ratios r vary largely depending upon presence of an alcoholic component contained in the food, the kind of the food can be reliably discriminated. <IMAGE>
