Abstract (en)
[origin: EP0624783A2] A lens inspector has an objective lens composed by front and rear lenses, a two-dimensional image sensor and an image forming lens for forming a point image of light passing through the objective lens. A lens to be inspected is disposed between a light source and an object focal point of the objective lens. The light source projects a light bundle onto the test lens in parallel with the optical axis of the objective lens, and the front lens of the objective lens is moved along the optical axis so as to shift the object focal point of the objective lens stepwise into a plurality of positions within a predetermined range including a normal focal point of the test lens therein. Brightness data of a point image formed on the two-dimensional image sensor is detected for each shift positions of the objective lens, and is used for judgment as to whether an actual focal point of the test lens is within a proper range. <IMAGE>
