Abstract (en)

[origin: WO9414368A1] The device according to the present invention consists of an ocular (1) connected to an optic fibre (2) sheathed with a means (4) for the moving of the visualizing end (3), that may be applied by means of a connecting element (8), between the handle (M) and the blade (LA) of the laryngoscope, so that said optic fibre (2) sliding along the blade through two guides (11) or similar, arrives to the larynx, undirectly visualizing said larynx and its aditus, even when this seems to be impossible with a direct vision, thus solving the problem of difficult and, at present, impossible intubations.
