Abstract (en)

The mouth 3 of the flask is fitted with a liquid transfer device (1) in the form of a stopper (2) with a pierceable disc (11) at the bottom. This bottom is open and extends in a tearable neck (4) which defines a closed tubular portion (6) that can be separated from the stopper (2). A tubular connected piece (9) with acutely pointed ends (9a, 9b) is arranged inside the porion (6), said tubular connecting piece being able to move axially in order to piece the disc (11) and having a widening (10) in the form of a piston which limits the movement of the piece (9) between the disc (11) and a seat (6a) of the tubular portion (6), from which extends a closed portion (8) which can be separated from said tubular portion. The connecting piece (9) is originally fitted with a cover (12), housed within the closed portion, which can move axially and which has a stop that prevents it prom being extracted from the tubular portion (6). To pierce the disc (11) and transfer a liquid from a tube or vial to the flask provided with the transfer device (1), the portion (8) is first separated to expose the cover (12). The tubular piece (9) is then pushed so that its end (9b) pierces the disc (11). Finally, the neck (4) is torn so as to separate the portion (6) and the cover (12) is extracted. <IMAGE>
