Abstract (en)  
[origin: WO9427487A1] The proposal is for a device for suspending especially a substantially longitudinally extended object comprising at least one clamping component (1) which can be directionally moved against a wall or another component (1) in order to hold the object firmly between them through its own weight. The at least one component has at least two vertically spaced supporting sections (3, 5) and/or at least one flat supporting region which can engage in one side of the object when it is clamped or suspended and force the object against the wall or the other component.
