Abstract (en)

[origin: EP0665168A1] The container (1) is of the form of a flask, pouch or tube intended to contain a liquid or paste which is distributed through an outlet hole (3) as a result of external pressure on its flexible wall (2). The wall has a longitudinal band (4) made of a more rigid material spread around the periphery. The band is extended on the container bottom (5) by a radial sector (6). It is also extended as far as the neck by a part (7) connected to the band through a transverse zone (8) at the shoulder marking the transition between the container body and the neck. The peripheral spread of the band is sufficient to maintain, inside the container, a longitudinal passage adjacent to the band, when opposite the internal wall faces touch each other after their collapse during distribution of the product.
