Abstract (en)
[origin: EP0682448A2] The user observes a liquid crystal display panel screen (2) positioned within an electronic viewfinder (3). An infrared LED that emits pulses of light (7) and a phototransistor are positioned in an eyecup (4) against which the user's eye is pressed. An ambient light detecting circuit (6) provides a control signal (C2) showing whether or not the user's eye is pressed against the eyecup and a control signal (C1) showing the amount of ambient light on the basis of the output signal of the phototransistor. A control circuit controls (10) the luminance of a backlight unit according to the control signals. When the user's eye is not pressed against the eyecup, the display luminance is reduced to zero and the display is turned off. The display luminance is enhanced only when the amount of ambient light is large. Thus, needless power consumption can be avoided, and the screen can be satisfactorily observed even if a large quantity of light enters into the ocular part where the ambient light is bright. Additionally a camera video tape recorder comprises an optical viewfinder, an LC-display means, a detection means and a control means. A user observes an object through the optical viewfinder means. The LC-display means is larger than the viewfinder means and is capable of displaying an image electrically for a number of users. The detection means detects an approach of a user to the display means. The control means controls the power of the display means in response to a wave detection output from the detection means.
