Abstract (en)

[origin: WO9517661A1] The present invention relates to a device for raising the level of a liquid containing a dissolved substance in a well or the like, as well as to a multiple well plate provided with such device. The device is characterized by a plurality of sleeves (1) with a variable thickness wall (4), said sleeves being opened at both ends and forming part of a support (7), and being insertable into the wells (2) of a plate (P). The device provides for a rise of the level of a liquid in a well in order to measure for example the optical density and may be used particularly to measure the optical density of a substance dissolved in a cell culture medium.
