Abstract (en)

[origin: WO9422411A1] The device is intended for the movement of the upper talocalcanean joint. It comprises two pedal shafts (1a, 1b) fitted horizontally in a bearing (6a, 6b) and extending coaxially to left and right on which a left and right pedal (2a, 2b) are radially secured integrally in rotation and driven by a gear motor (3) in such a way that the rotary movement of the motor shaft (4) is converted into an alternating contrarotatory oscillating movement of the left and right pedals (2a, 2b) between terminal positions within a restricted angular region. In addition there are means (5; 8; 9; 10) which limit the torque transmitted from the motor shaft (4) to the pedal shaft (1a; 1b) on the forced stoppage of a pedal (2a, 2b) resulting from the reaching of an end position in the range of movement of a talocalcanean joint to a selectable maximum value, the force/travel diagram of the means (5; 8; 9; 10) preferably having a torque limitation characteristic which is substantially flat when the selected salient point is exceeded.
