Abstract (en)

[origin: EP0693604A1] The mechanism consists of a housing (14) containing a moving actuator for a lock, and a stop (1) which prevents incorrect operation of the lock by immobilising the lock in the unlocked position. This comprises a wedge (22) which is released by direct or indirect movement of the door/window frame. There is a support (24) for the wedge, and connectors (25) which co-operate with matching connecting members (26) fixed to the rear wall of the lock housing. The wall has an aperture in it to enable the wedge to co-operate with the moving actuator. <IMAGE>
