Abstract (en)

[origin: EP0700781A2] The printing system is used to print information on the outside surface of a cylindrical object (32), rotated about its axis, via a programme-controlled screen printing machine. A marking carried by the object is detected during its rotation about its axis, with the corresponding angular position used as the zero reference point for the object rotation and entered in a memory of the programme control. The required printing position is obtained by rotating the object through a defined angle from the stored reference position, with coordinated displacement of the printing screen (18).
