Abstract (en)

[origin: WO9504204A1] An electrical operator device for opening and closing a window comprises a case (6) connected with the main frame structure and a push element (12) extending from there in the direction of the frame. The operator device is disengageably connected with an operating member (4) for a locking mechanism, which operating member is pivotally mounted on the frame, by means of a coupling device comprising a male part having a head portion (20) connected with the free end of the push element, for disengageable engagement with a female part with a recess (22), in connection with an insertion opening (21), mounted on the operating member (4). The head portion (20) of the male part and the recess and opening (21) of the female part are elaborated and adapted to each other in such a way that the head portion (20), in a position of the pivotal operating member (4) corresponding to activation of the locking mechanism when the window is closed, can be guided into and out of the opening, but in a swung-out position of the operating member (4) in relation thereto, corresponding to a release of the locking mechanism, is prevented from passing out through the insertion opening. The operator device is controlled in such a way that in the first mentioned position, the male part is disengaged from the female part.
