Abstract (en)

[origin: EP0711855A1] To contain and store an overlength in the warps, between the creel and the warping beam, each warp yarn has a defined tension through a brake at the creel. The reverse movement of the warping beam is slower than the working speed of the yarn store rollers, and the difference between their speeds is equalised through the length difference by a further pull action on the warps from the creel under brake tension.
