Abstract (en)
[origin: EP0719717A1] The system comprises a slide (4) for leading the objects onto an inclined receptor plane (1). The receptor plane is pivoted along its lower side about a transverse axis (X). This allows it to pivot downwards from an upper position a and oppose a return torque towards the upper position. When an object of mass greater than a certain threshold is led onto the receptor plane the plane momentarily lowers until the torque the object exerts on it becomes less than the torque returning the plane to its upper position. The object is braked by friction on the receptor plane whilst it is lowering.
