Abstract (en)

[origin: EP0726147A1] The control has an electronic data processor. This has a data input for different print parameters e.g. board height, type of printing material, type of solution, mode of operation of individual print mechanisms, and type of ink etc. It also has a data memory to store the input parameters. A computing unit calculates control parameters e.g. proportion of solution, proportion of water and dispensing quantities, from the input print parameters, for that particular washing device. The computing unit accesses tables of characteristic values stored in the memory and/or processes algorithms which allocate control parameters to the print parameters according to predetermined rules. The control also has a data output for the derived control parameters. Preferably, the control parameters can be varied by inputting control commands.
