Abstract (en)

In the device coins corresponding to a payment, thrown into a hopper, fall on a recessed disc and each lodge in one of the recesses. If two coins are superposed in one recess, the upper coin is deflected outwardly by a slot and then raised by the inclined bottom of this slot to finally be ejected from the recess. The coins are then, as a function of the result of a detection, oriented toward one of the other of two compartments of an annular display which surrounds the separation disc. At the end of each payment the annular display turns a fraction of a turn to bring the two compartments into a presentation position, while two empty compartments are presented to receive the following payment, and the coins corresponding to the preceding payment arrive at a transmission position for example towards collection boxes. The drive of the movable portion of the display is effected by its radially outer edge. The central portion comprising the separator disc and its drive motor can swing downwardly to eject foreign bodies. In case of a questioned coin, or if the movable portion of the display is in the course of rotation, the coin is returned to the detector instead of proceeding to the display.

Abstract (fr)

L'invention concerne un procédé de reconnaissance d'objets du type pièces de monnaie, dans lequel on fait passer les objets un à un dans le champ d'action d'un détecteur (31) appartenant à un dispositif de reconnaissance (1), et en fonction de la réponse du détecteur au passage de chaque objet, on dirige sélectivement l'objet vers au moins une sortie (43, 44) du dispositif de reconnaissance (1) et respectivement on renvoie l'objet dans le champ d'action du détecteur (31). <IMAGE>
