Abstract (en)  
[origin: WO9534968A1] The aim of the invention is to develop a system and method which can work with variable encryption algorithms and which ensures the secure transfer of the algorithm without it being detected and prevents the algorithm without it being detected and prevents the algorithm being broken. This aim is achieved by virtue of the fact that the decoding device consists of an integrated circuit (1) associated with a central processing unit (2), an internal non-readable volatile random-access memory (3) used as working memory and an internal non-readable non-volatile read-only memory (4) plus an interface (5), each decoding device differing from every other by the content of the ROM (4) and being partly integrated in an integrated circuit (1) and that the interface (5) is located between the central processing unit (2) and the personal computer (6) and connected, together with central processing unit (2), to the personal computer (6) by a data path (a).
