Abstract (en)  
[origin: EP0769439A1] Locking devices (R1,R2,H1,H2) secure the positioning crank (K) in its end position after completion of a positioning movement. The positioning crank is connected in positive engagement with the positioning slide (ST) by a coupling component (Z) adjustable in its distance from the rotary axis. The positioning crank is formed as an at least two-armed lever, of which a lever arm which is not connected to the positioning slide is formed as a sector of a circle, through the centre point of which runs the rotary axis. An unlocking disc (E) arranged parallel to the circular sector is preferably of the size of that sector, which receives a torque (M) to be transmitted from the drive component to the positioning crank.
