Abstract (en)

[origin: EP0770573A2] The load detection device uses a signal (40) induced in the winding (27,28) of the electric motor of the lifting mechanism which is not energised for driving the latter. The momentary loading is determined from the frequency of a given spectral peak of the induced signal frequency spectrum, with a filter used for suppression of a given spectral range of the induced signal, e.g. the spectral range below the frequency of the energising voltage for the energised motor winding.
