Abstract (en)  
[origin: EP0811402A1] The retainer (1) comprises a dorsal support (7) providing rear support for the lower leg. It has a base (8) which takes the boot sole. The dorsal support is articulated on the base along an axis (Y-Y'). A control peg (11,22) fixed to the boot (2) causes articulation of the dorsal support relative to the base by engaging an arm (18) in the dorsal support. This causes leverage relative to the Y-Y' axis. The dorsal support is articulated from an open position to a closed position in the direction from back to front when the sole is displaced towards the board during fitting. A spring (24) moves the dorsal support relative to the base in accordance with the front to back articulation. A stop (25) limits articulation of the dorsal support in the front to back direction. The dorsal support has an indentation (26) at the level of the boot heel.
