Abstract (en)

[origin: WO9634368A1] An electronic gaming device has one or more housings with at least one result-encryption key stored therein, as well as a portable article adapted for co-operating with the housing and with a set of authenticatable digital game data representative of a game stored therein. The portable article is made to co-operate with the housing. The set of game data is authenticated in the housing and stored in a working memory of the housing so as to authorise the progression of the game in the housing. After completion of at least part of the game, result information dependent on said game is encrypted in the housing by means of at least one result-encryption key, and the encrypted result information is stored in a result memory of the portable article, which then co-operates with a validation station capable of accessing the result-encryption key, whereafter said station verifies the result information.
