Abstract (en)
[origin: WO9636492A1] In a stitching device for transversely stitching product sections in a folding machine downstream of a rotary press, the aim is to permit no relative movement between stitching clamps and product sections during the stitching process. This is achieved according to the invention by a binding device in which a stitching head (22) involved in the current stitching process performs a movement directed radially to a counter-cylinder (4).
