Abstract (en)

[origin: WO9712040A1] A method to render mammalian, particularly endothelial cells less susceptible to platelet- and leukocyte-mediated injury and inflammation is described, comprising genetically modifying the cells by inserting DNA encoding a transdominant inhibitor of a Re1A (p65) protein, and expression functional inhibitor in the modified cells under cellular activating conditions, whereby Re1A (i.e. NF kappa B) transactivation of genes is suppressed, and corresponding proteins and DNA therefor. The method, which can be carried out in vivo, ex vivo or in vitro, has use in allogeneic or xenogeneic transplantation as well as to treat systemic or local inflammatory conditions.
