Abstract (en)
[origin: EP0890379A1] The fastenings (260,270) are fixed to the ski so that they swivel on at least one transverse axle (230). A cam (280) controlling the articulated movement between the fastenings and the ski has a surface (281) which is convexly curved at least in the area of the ski's longitudinal direction. When the boot is lowered, the cam is positioned between the boot and ski in front of the middle of the ski. In one stage of the cam's articulated movement, the distance between the heel and the support line (285) of the cam increases as the heel is raised.
