Abstract (en)

[origin: EP0892215A2] The method uses at least one overheating sensor (12). The output signal from the sensor is led to a control unit (13). The control unit, corresponding to an instantaneous experienced heating power of the heater, carries out a comparison with a typical switching threshold for this heating power. Several switching thresholds are stored in a storage of the control unit, and on the basis of at least one of the parameters typical for the respective heating power, are computed by the control unit. The switching thresholds are defined on the basis of two different specified value pairs, temperature or temperature difference or temperature gradient/heating power, by establishing a graph connecting these value pairs.
