Abstract (en)

The expiration of the lifetime of a combustion apparatus is determined based on a carbon monoxide density (CO) which is detected by a carbon monoxide detector during combustion when a ventilation system is little affected by wind and a predetermined reference volume or more of fuel is supplied. For example, the combustion performance and the lifetime of the combustion apparatus 10 are examined based on a count by which the CO density measured during combustion exceeds an abnormality value which represents abnormal combustion. <IMAGE>
