Abstract (en)  
[origin: EP0899885A2] The invention relates to encoding and decoding methods for a high-density data storage device. In the encoding and decoding methods, input 8-bit data is compressed and error-correction encoded to be immunized to noise and other signal-distortion causing factors. The error-corrected data is encoded to 9-bit codewords modulated to be suitable for the channel characteristics of the storing device. A signal is generated for the input 8-bit data encoded to modulation codes. The generated signal is pre-compensated and recorded. The generated signal is processed to be easily detected by reproducing the 9-bit codewords. The processed signal is detected to minimize an error rate. The detected signal is decoded according to channel characteristics, and recovered to the input 8-bit user data through error correction and compression decoding. The 9-bit codeword encoding step includes the substeps of generating a codeword with a code rate of 8/9 and MTR of 3, generating a codeword with a maximum zero run length k of 7, determining whether the fifth bit of the 9-bit codeword having a code of 8/9 and an MIR of 3 and a K of 7 is zero, and going to mapping the first four bits and last four bits of the input 8-bit user data to the first four bits and last four bits of the codeword without variation if the determination result is zero and if the determination result is not zero, mapping input 8-bit user data for fifth bits that are not zero to most approximate 9-bit codewords which have ones in the fifth bits thereof, and applying input and output lookup tables between the input 8-bit user data and the 9-bit codewords according to the mapping results, and simplifying them to Carnot maps. The input 8-bit data decoding step is performed by reversely performing the step for encoding the 8-bit user data to the 9-bit codewords. <IMAGE>
