Abstract (en)
[origin: WO9806011A1] In order to optimise half-tone reproduction by optimising toner deposit intensity in electrophotographic printers and copiers, a toner grid is generated on a photoconductor before and during a printing or copying process, once basic values have been set, and the optical density of the toner grid is determined. A bias potential is then lowered with respect to a momentary value when the optical density exceeds a set value and the bias potential is higher than a minimum value. The photoconductor is discharged, cleaned and charged again before returning to the initial state.
