Abstract (en)

[origin: EP0967432A2] The switching arrangement is arranged at the opposite end of the cylindrical torch body from the lamp. A sliding element (7) can move over a restricted longitudinal path, is supported under spring (9) force on a rod battery (4) base and has an actuating knob (8) at its free end via which the sliding element can be actuated against the spring for temporary contact. A block part (11), against which the sliding element is forced by the first spring, can be moved transversely to the sliding element against a second spring (14) force and has a groove in its contact surface engaged by the sliding element to effect a permanent switching action when the block is displaced against the second spring.
