Abstract (en)

[origin: EP0972986A2] The method is for use in heating systems where the flame holder separates the air/mix chamber(1) from the combustion chamber(2). A throttle is arranged in the air chamber upstream of the flame holder(3) to increase the acoustic damping and to decouple the combustion chamber from the mixing chamber. The throttle(5) has a variable cross section. The throttle opening is varied in dependence on the air/mixture flow volume such that the pressure gradient (dy/dx) of the throttle with increasing flow volume is always smaller than that of a throttle with constant cross section according to the relationship dy/dx is less than $2 \text{ const } x$. An Independent claim is also included for a burner operated according to the method. The throttle is varied through the use of an external control using an actuator.
