Abstract (en)

[origin: WO9745142A1] A method of preventing graft-versus-host disease in a patient being treated for relapsed or persistent leukemia. The method comprises administering to a host allogeneic T-cells genetically engineered to include a polynucleotide encoding a negative selective marker. Prior to the occurrence of graft-versus-host disease, an interaction or chemotherapeutic agent is administered to the host, which kills the genetically engineered T-cells, thereby preventing the occurrence of graft-versus-host disease. Such method also may be employed in connection with the treatment of any disease or disorder wherein the treatment includes bone marrow ablation followed by the administration of a T-cell depleted bone marrow transplant.
