Abstract (en)

[origin: EP0984414A2] The device detects body function, periodically detects current position, and triggers an emergency call if the detected data are abnormally different from the reference data. The device (1) comprises a communication unit (2), a position recognition unit (7) and a manually operated alarm switch. The device includes at least one sensor (3) for identifying body functions, and a store (4) containing reference body function data. The sets of data are compared in a diagnosis unit (5). An emergency call is triggered if the detected data are abnormally different from the reference data. The current position, the temporarily stored position statement and detected sensor data are sent with the emergency call. An Independent claim is included for a emergency call outputting method.
