Abstract (en)

[origin: WO9815293A2] Proteins are modified with soluble polymers to change their biological properties, such as to render them less immunogenic and longer-lived in the body. The modification is by a strong, but non-covalent complexation between a metal chelate and an oligohistidine tag which is engineered into the protein. This method of protein modification leads to homogeneous preparations which can be readily prepared in large quantities.
