Abstract (en)

[origin: US6189688B1] A multi-chamber dispensing container for storing at least two substances in an impervious and sterile environment. The container has a tubular body, with a bottom end and an end having an opening. At least one means of occlusion having a continuous outer edge is disposed in an oblique position inside the body between the ends prior to activation of the container. The means of occlusion seals the body imperviously and divides it into two chambers, each containing a substance. The container further has a means for dispensing the substances contained in the body, these means being disposed near the end presenting the opening and sealing this end imperviously. The means of occlusion has two different areas, one of which is partially tearable under the effect of activating pressure from the fingers, the other being designed so as to not tear under the effect of the pressure. This second area maintains the means of occlusion in place within the body after activation.
