Abstract (en)
[origin: WO9923610A1] An image represented by color values corresponding to the pixels of a rendering screen is rendered in response to three-dimensional graphics data. The three-dimensional graphics data include polygon data and texture data. The texture data define a texture and include texture size data and pattern data. The pattern data represent multiple instances of the texture. Each instance has a different resolution. The pattern data constitute a significant majority of the texture data. The polygon data, the texture size data and the pattern data representing the lowest-resolution instance of the texture are initially loaded. An initial rasterizing operation is performed using the polygon and texture size data to generate and to store a texture identifier and texture coordinates for each pixel of the rendering screen. A display-and-load operation is repetitively performed until either the color values of all the pixels of the rendering screen are generated using different ones of the pattern data, or the pattern data of at least part of the highest-resolution instance of the texture have been loaded. In the display-and-load operation, the color values representing the image are generated using the pattern data of a highest-resolution instance of the texture previously loaded. In response to the texture coordinates stored for the rendering screen pixels, the pattern data of a next-higher resolution instance of the texture required to render at least parts of the image with a higher resolution are identified, and the identified pattern data are loaded.
