Abstract (en)

[origin: FR2785691A1] The invention concerns a method for generalised triggering of administrative action on a distributed computer system managed by a software manager (30) using an information base stored in storage means and objects defining a main domain (D0) comprising at least two subdomains (D1, D2), each subdomain (D1, D2) comprising a group of machines (20, 40) and/or at least of another subdomain (21, 41). The invention is characterised in that the method comprises an initialising step comprising: a first associating and storing step wherein each action for administering the main domain is associated with a specific action, for each subdomain (D1, D2) the different specific actions having the same functionality corresponding to the performance of the administrative action; a second step which consists in creating and storing for each specific action at least a named set of parameters (P1, P'1, P2, P'2) comprising the parameters required for implementing the specific action, each name the parameter set being identical for all the specific actions of one common administrative action; and an implementing step.
