Abstract (en)

[origin: EP1052305A2] Carbide-forming metallic melt solidification kinetics and matrix composition control comprises alloying with aluminum in amount dependant on the carbon and group V element contents. An alloying process, for controlling the solidification kinetics and matrix composition of carbide-forming metallic melts, comprises alloying the liquid metal with 0.3-2.6 weight % aluminum, depending on the carbon content in the range 0.6-1.7 weight % and on the group V element content of up to 4.3 weight %, with the proviso that $Al = CxANxF$, where Al = the aluminum content (weight %), C = the carbon content (weight %), AN = the Nb equivalent ($AN = 0.3 + 0.1 \text{ weight \% V} + \text{weight \% Nb} + 1.12 \text{ weight \% Ta}$) and F the activity range factor ($F = 0.7$ to 1.3). An independent claim is also included for a metallic material, especially produced by the above process, having high hardness, wear resistance and toughness and containing C , one or more group V elements, Al , optionally Si, Cr, Mo and W, balance one or more of Mn, Fe, Ni and Co and impurities, the C content being up to 1.7 weight %, the group V element content being up to 4.3 weight % and the Al content being 0.3-2.6 weight % with the proviso described above.
