Abstract (en)

[origin: EP1091349A2] The method involves using a multi-layer self-organising neural network with feedback. A minima detection layer, a reaction layer, a diffusion layer and an integration layer define a filter function ($F(f,T)$) for noise filtering. The filter function is used to convert a spectrum $B(f,T)$ free of noise, into a noise-free speech signal ($y(t)$) by inverse Fourier transformation. The signal delay caused by processing the signal is so short that the filter can operate in real-time for telecommunication. All neurons are supplied with an externally set parameter K , the size of which defines the degree of noise suppression of the whole filter. An Independent claim is included for an apparatus for noise suppression during speech transmission.
