Abstract (en)  
[origin: WO0000687A1] The invention relates to a method and a device for separating adjacent threads which are stretched in a first and a second location and substantially form together a surface. In order to provide a method and a device serving to reliably separate threads from a yarn layer even when the threads consist of so-called untwisted multifilaments, several threads are grasped with separating means (5, 15, 25, 35) at least in one location, whereupon the grasped threads are subjected to different relative accelerations substantially in their transversal direction. After one or several separation processes, the first thread can be easily grasped, e.g. by a drawing-in hook and then removed from the layer.
