Abstract (en)
[origin: EP1142513A2] It is a heat distributor for personal use which comprises a reservoir for water or other fluid, arranged into a container. The fluid is electrically heated through electrical resistors arranged into the reservoir and a circulation pump makes the fluid flow from the reservoir, through a tubular flue, into a heat storage member, consisting for example of a portion of tubular element shaped as a spiral. The latter is connected to the above reservoir through a further return flue. The heat is distributed through outside delivery starting from the storage member. Thanks to such device it is possible to easily and safely obtain the heating of surfaces of sofas, beds and the like, for a greater comfort of its user, in particular during winter season. <IMAGE>
