Abstract (en)

[origin: WO0064244A1] When piglets are set out in their own self-feeding sties, e.g. 30 piglets per sty, it takes some weeks before the animals can operate ordinary self-feeding devices, and during this time use is made of devices of another type, from which by remote control and motor power an automatically-controlled dosing of the feed can take place. With the invention, a more or less extensive integration of the two relevant types of devices is disclosed, based among other things on the recognition that by frequent automatic feeding in relatively small amounts, the crowding of the piglets at the feeding trough can be avoided, which otherwise makes it necessary to configure automatic feeding aggregates with relatively large troughs. Such a large trough can, however, form part of a replacement set in connection with a device part for the provision of active feeding.
