Abstract (en)

[origin: WO0033236A1] A computer-controlled method of reducing the risk connected with a health condition of a patient includes determining an association between the patient's profile (250) which contains current information about the patient's condition, and a protocol domain space (200), accessing a protocol from the protocol-domain space (200) responsive to the association, and updating the profile responsive to the protocol. The protocol domain space (200) is three-dimensional and is bounded by a 'risk classification' axis (201), a 'clinical area' axis (203), and a 'content type' axis (205). A data cell (227) is located at the intersection of the coordinates and contains a set of protocols (229) each of which is designed specifically for its location in the protocol domain space (200).
