Abstract (en)

[origin: WO0076046A1] In power circuit breakers which comprise a current transformer (6) having an ironless current detection coil (7) and an integration circuit (8) connected in outgoing circuit to said current detection coil (7), a faulty tripping can result due to the unavoidable time constant of the integration circuit (8). This is prevented by the inventive method in which the instantaneous values of the current are detected and stored in established periodic intervals (n, n+1, n+2). The stored measured values are compared according to polarity and magnitude. If the stored values of the same polarity prove to be monotonically decreasing, it is then assumed that an equivalent term is output by the integrator (8), and a trip blocking signal is input into the electronic trip of the power circuit breaker.
