Abstract (en)

[origin: WO0120453A1] Method and apparatus for modifying the program flow of microinstructions residing in a static memory device. When microinstructions from the static memory device need to be modified, a jump point register is used to hold a jump point address that triggers an interrupt event. When the current program counter contains an address equal to the jump point address and the jump point register is enabled, an interrupt event is generated that redirects the program flow away from the static memory device to a programmable memory device. Rather than using the interrupt to indicate the occurrence of an external event, the interrupt is used to bypass portions of the microinstructions residing in the static memory device.
