Abstract (en)  
[origin: CA2389720A1] An inertial motor (17) utilizes a smoothly coordinated circular motion and converts the motion of circulating weights (9) into a unidirectional series of impulses that drive a vehicle (8) forward. Weights (9) located on an armature are guided on tracks along radial paths from center of the armature. The position of the weights (9) is controlled electromagnetically by solenoids (C1, C2, C3, C4). The solenoids (C1, C2, C3, C4) are energized and de-energized at stations (13) along their circular route in such a manner as to transfer linear momentum to the axis of the armature.
