Abstract (en)

[origin: EP1265042A2] The system has at least one compressor unit whose output branches into one or more sub-flows of vapor with higher coolant concentrations at a pressure below the system's high pressure level feeding an absorber unit(s) in which admixture of absorbent and condensation takes place. The compressed high pressure vapor is fed to the expeller in which separation of cooling, absorber material occurs to output approximately pure saturated coolant vapor. The system has at least one compressor unit (1), liquefier (2), evaporator (4) and absorber unit (6) and an expeller (7). The compressor unit output branches into one or more sub-flows (10) of vapor with higher coolant concentrations at a pressure below the system's high pressure level that are fed into one or more absorber units in which admixture of absorbent and condensation takes place. The compressed high pressure vapor flow is fed to the expeller, in which separation of the cooling and absorber material takes place so that an approximately pure coolant vapor emanates from the expeller in a saturated vapor state.
