Abstract (en)
[origin: WO0234603A1] The invention relates to an upper positioning device for a sliding side (6) which is guided out of or into its closing position in a guide rail by means of at least two rollers (8). In the closed position of the sliding side (6), a parallelogram linkage system consisting of two pivoted levers (2, 5) and a bridge (3) linking the same is provided in the area of each roller (8), one of said pivoted levers (2, 5) being permanently connected to a shaft (1) that is shared by the parallelogram linkage rods. The parallelogram linkage system can be pivoted out of a lowered position into a raised position, the sliding side (6) having a cap (10) at its top end which covers the parallelogram linkage system at least in sections. A first part (11) of a first guide rail (7) is located on said cap (10), this guide rail having at least two parts (11) which can be moved in relation to each other and which are flush with each other. A second guide rail (9) is connected to the parallelogram linkage system. In the raised position, this second guide rail essentially adopts the position of the first part (11) of the first guide rail (7) in the lowered position and is flush with the second part (11') of the first guide rail (7).
