Abstract (en)

[origin: EP1341323A2] An optical signal multiplexer/demultiplexer (96) using an orthogonal pseudorandom (PRN) coding scheme for optical mode modulation to produce a plurality of independent optical signals $\{S_i\}$ that may be combined into one multiplex signal (106, 110) for transmission over an optical fiber (98) to the receiving end (112), where the multiplex signal (106, 110) may be demultiplexed by relying on the orthogonal properties of the PRN code to isolate each independent optical signal S_i from the transmitted multiplex signal (106, 110). In channels subject to mode modulation distortion, one of the signal components may be used as a pilot signal (72) to obtain a correction for channel mode modulation distortion. The PRN optical signal multiplexer/demultiplexer (96) is particularly useful with polarization mode modulation. <IMAGE>
