Abstract (en)

[origin: WO0244822A1] The invention relates to a method and a device for calculating in advance the process variables of an industrial process. The method, which consists of at least one empirical model and a core model, is subsequently adapted and optimised using a model that has a partial inverse structure in relation to the core model. The empirical models are optimised by means of adaption or training algorithms, which, in addition to known process parameters, have the empirical variables calculated by the partial inverse core model as basic input variables.
